# 1 Introduction

AECOM was commissioned by the London Borough of Lewisham to install and maintain a network of NO<sub>2</sub> diffusion tubes to assess the spatial variation of nitrogen dioxide (NO<sub>2</sub>) concentration within the Borough. The diffusion tube network comprises of 34 NO<sub>2</sub> diffusion tubes at 32 locations. One of these locations is a triplicate site and the remaining locations are single sites. The diffusion tubes were exposed for periods of between 4 and 5 weeks in accordance with the UK NO<sub>2</sub> Survey Timetable. The results of the survey provide Lewisham Borough Council with valuable monitoring data for use in their Local Air Quality Review and Assessment (LAQM) process.

This report outlines the results of the survey for January 2014 to December 2014, inclusive. The spatial variation in  $NO_2$  concentration throughout the Borough is discussed and the annual mean values for each location are compared against the annual mean objective for  $NO_2$  to indicate locations that may be likely to exceed the objective. Monthly concentrations are examined for evidence of seasonal trends.

Limit values and air quality objectives for nitrogen dioxide and oxides of nitrogen (NO<sub>X</sub>) were set out in the First Daughter Directive (1999/30/EC) and subsequent revisions. An annual mean NO<sub>2</sub> objective was set at 40  $\mu$ g/m<sup>3</sup> to be achieved by 1<sup>st</sup>January 2010. A 200  $\mu$ g/m<sup>3</sup> hourly mean standard not to be exceeded more than 18 hours per year was also outlined, to be achieved by the same compliance date. These objectives were reiterated in the 2008 Directive on ambient air quality and cleaner air for Europe (2008/50/EC).

The UK has published its own Air Quality Strategy<sup>1</sup>, which detailed the UK's position on nitrogen dioxide. The UK air quality objectives differ from the European objectives only in their compliance dates; the UK objectives were to be achieved by the end of 2005. European and UK air quality objectives have also been set for oxides of nitrogen for the protection of vegetation and ecosystems. A summary of the principal air quality objectives for NO<sub>2</sub> and NO<sub>X</sub> is given in Table 1.

		UK Air Quality Objectives				
Pollutant	Standard / Concentration	Measured as	Date to be achieved by and maintained thereafter			
Nitrogen Dioxide	200 µg/m <sup>3</sup> not to be exceeded more than 18 times a year	1 Hour Mean	31.12.2005			
	40 µg/m <sup>3</sup>					
Nitrogen Oxides (for the protection of vegetation)	30 µg/m <sup>3</sup> Annual Mean		31.12.2000			
	EU Air Quality Objectives					
	Standard / Concentration	Measured as	Date to be achieved by and maintained thereafter			
Nitrogen Dioxide	200 µg/m <sup>3</sup> not to be exceeded more than 18 times per year	1 Hour Mean	1 January 2010			
	40 μg/m <sup>3</sup>	Annual Mean				
Nitrogen Oxides (assuming as nitrogen dioxide)	30 µg/m <sup>3</sup>	Annual Mean	19 July 2001			

Table 1	UK and EU Air Quality Objectives for NO <sub>2</sub> and NO <sub>X</sub>

# 3 Monitoring Methodology

#### 3.1 Description of Network

The Lewisham Diffusion Tube Network has been maintained by AECOM since January 2011. In 2011, the network consisted of 47 locations, in which one of these was a triplicate co-located site at the automatic monitoring stations in New Cross Road and the remaining were single sites, using a total 49 diffusion tubes. In 2012, the network was reduced to 34 diffusion tubes at 32 locations, comprising of single tubes at 31 locations and triplicate co-located at New Cross Road continuous monitoring station. During 2014, diffusion tubes throughout the Borough have been deployed and collected at 4 to 5 weeks intervals in accordance with the UK NO<sub>2</sub> Diffusion Tube calendar<sup>2</sup>.

The locations of the diffusion tubes are geographically illustrated in Appendix A.

#### 3.2 Procedures and Site Changes

All diffusion tubes used in the network were stored in a refrigerator prior to deployment and after collection to reduce the possibility of degradation of the chemicals involved. Tubes subject to contamination (e.g. spider webs, foreign bodies, etc.) or vandalised have also been excluded from the final dataset.

In June, July and August 2014, no access was granted to the diffusion tube at Dartmouth Road, located within the school grounds, due to construction works being conducted on site. This tube was relocated in October 2014 to be at a more accessible location, within the school fence line but at the entrance of the school.

#### 3.3 Tube Preparation, Analysis and Laboratory QA/QC

The diffusion tubes were supplied and analysed by Gradko International Ltd, using a 50% triethanolamine (TEA) in acetone method. Gradko participates in the Health and Safety Laboratory's (HSL) Workplace Analysis Scheme for Proficiency (WASP) programme for diffusion tubes, which provides a Quality Assurance / Quality Control (QA/QC) framework for local authorities carrying out diffusion tube monitoring as a part of their local air quality management process. The percentage of results submitted from Gradko International Ltd which were subsequently determined to be satisfactory was 100% for all tests in Rounds 117-124 (April 2012 -March 2014)<sup>3</sup>.

#### 3.4 Factors Affecting Diffusion Tube Performance

 $NO_2$  diffusion tubes are an indicative monitoring technique, as they do not offer the same accuracy as the reference method for  $NO_2$ , the automatic chemiluminescence analyser.  $NO_2$  diffusion tubes are affected by several factors, which may cause them to exhibit bias relative to the reference technique.

Over-estimation may be attributed to one of the following three interfering factors:

- The shortening of the diffusive path length caused by the wind;
- The blocking of UV light resulting in reduced NO<sub>2</sub> photolysis in the tube; and
- The interference effects of peroxyacetyl nitrate (PAN).

Under-estimation can be caused by the following factors:

- Increasing exposure period, and is thought to be due to degradation of the absorbed nitrate with time;
- Insufficient extraction of nitrite from the meshes;
- The photochemical degradation of the triethanolamine-nitrite complex by light, although this is minimised by the use of opaque end-caps; and

 <sup>&</sup>lt;sup>2</sup> Defra, Local Air Quality Management, Diffusion Tubes, Nitrogen Dioxide Diffusion Tube Monitoring, Calendar of Suggested Exposure Periods 2014. Available at http://laqm.defra.gov.uk/diffusion-tubes/data-entry.html
 <sup>3</sup> Summary of Laboratory Performance in WASP NO2 Proficiency Testing

Scheme for Rounds 117-124. Available at: http://laqm.defra.gov.uk/documents/LAQM-WASP-Rounds-117-124-(April-2012--March-2014)-NO2-report.pdf

- The solution used. For example, 50% solution of TEA in water has been reported to lead to comparatively reduced NO<sub>2</sub> uptake.

There are a number of additional factors that may also affect diffusion tube performance including time of the year, the exposure setting (i.e. sheltered or open sites), the proximity to roads, the preparation method and analytical laboratory used, the exposure concentration and the ratio of  $NO_2$  to  $NO_x$ .

#### 3.5 Data Validation and Data QA / QC

Validation of diffusion tube readings is vital to ensure public confidence in the measurements produced. Validation is achieved through the following steps described in sub-sections below.

#### 3.5.1 Blanks

The laboratory reserved a set of diffusion tubes for use as laboratory blanks for each dispatches of tubes to the user. These are kept in sealed containers in a refrigerator and analysed with the exposed tubes to provide a measure of nitrite concentration on unexposed tubes.

One travelling blank was taken to site during each of the monthly changeovers. These tubes accompany the user during tubes changeover but are not themselves exposed. The purpose of using field blanks is to identify possible contamination of the tubes during transportation or in storage by the user.

Laboratory and field blanks were routinely screened by AECOM to ensure quality of data. Neither the laboratory blanks nor the travel blank results were subtracted from the results of exposed tubes, in accordance to the Local Air Quality Management Technical Guidance (LAQM.TG(09))<sup>4</sup> and the Diffusion Tube Practical Guidance.

### 3.5.2 Rejection of Diffusion Tube Results

Diffusion tube results obtained for each month were checked to meet the following criteria for inclusion in the final dataset:

- Correct calculation of exposure hours;
- Concentrations less than 3  $\mu$ g/m<sup>3</sup> were rejected as these concentrations are unlikely to occur in an urban area.
- Concentrations at the high end were not routinely rejected unless good evidence can be shown to prove the spurious results.
- Exposure records were checked for possible explanation of any unusual results (e.g. foreign objects, bonfires, pollution episodes, construction works, tampering, etc.).
- For triplicate site, diffusion tube that exhibits poor precision (>20%) was excluded from the final dataset. For single sites, professional judgement was used to accept or reject the results based on observations made during site visits.

#### 3.5.3 Bias Adjustment Factor

Diffusion tube monitoring is indicative and does not offer the same accuracy as the reference method for monitoring  $NO_2$  i.e. using an automatic chemiluminescence analyser. Several factors could affect  $NO_2$  concentrations measured with diffusion tubes, which may cause them to exhibit bias (over-read or under-read readings) relative to the reference method (see Section 3.4). To correct this bias, comparison of the  $NO_2$  concentration as measured by diffusion tubes is made with continuous monitoring data to derive a bias-adjustment factor.

Bias adjustment factor can be obtained using the Nitrogen Dioxide Diffusion Tube Bias Adjustment spreadsheet<sup>5</sup>, which is updated periodically and collates the bias-adjustment factors obtained in co-location studies conducted

<sup>&</sup>lt;sup>4</sup> Defra, Local Air Quality Management Technical Guidance LAQM.TG(09), 2009.

<sup>&</sup>lt;sup>5</sup> Defra, National Diffusion Tube Bias Adjustment Factor Spreadsheet (Version 03/15). Available at http://laqm.defra.gov.uk/bias-adjustment-factors/national-bias.html

nationally. It can also be derived locally through co-location of diffusion tubes with automatic analysers and compared the results obtained from both methods of monitoring.

Further details of the monitoring sites used and the derivation of the factor can be found in Appendix B and Appendix C. The local bias factor was applied to all diffusion tube results in the period unless indicated otherwise.

## 3.6 Site Designations

#### 3.6.1 Site Designations

The designation of site types is used to compare different locations statistically. Sites were categorised as kerbside, roadside, near road (intermediate) and urban background sites according to the definitions given in the "Practical Guidance for Diffusion Tube Monitoring" <sup>6</sup> report. These definitions are reproduced in Table 2 below.

Туре	Definition
Kerbside	Within 1m of the kerb.
Roadside	1-5m from the kerb edge.
Intermediate (or 'Near Road' sites)	More than 5m from the kerb of a busy road but air quality is likely to be affected by the nearby busy road.
Urban Background	> 50m from any major source of NO <sub>2</sub> , such as multi-storey car parks;
	> 30m from any very busy road (> 30000 vehicles per day);
	> 20m from any busy road (10000 – 30000 vehicles per day);
	> 10m from any main road (quiet roads e.g. within residential estates are acceptable; and
	> 5m from any area where vehicles are likely to be idling.

 Table 2
 Site Type Designation Criteria

<sup>&</sup>lt;sup>6</sup> Diffusion Tubes for Ambient NO<sub>2</sub> Monitoring: Practical Guidance for Laboratories and Users. AEA Techonology, February 2008.

#### 4.1 Data Capture

Data capture rates for the Lewisham Diffusion Tube Survey Network during 2014 were generally high, achieving an overall average of 95% for all site types. The lowest data capture was reported for the tubes at Sydenham School (SCH021) with 58% and at Whitburn Road (L10) with 67% capture rate (Appendix B). The tube sited at Sydenham School location was found missing in May and building work prevented access in the months June-August and October. The tube was re-located in October to ensure further building work did not influence data capture. The tube at Whitburn Road was found missing in the months September-December 2014. The results from these locations have been annualised in accordance with Defra Guidance LAQM.TG(09) (Appendix C).

Sites recording lower than 100% data capture were as a result of tubes being stolen, clips being vandalised or data not being included in the final dataset (see Section 3.5.2).

#### 4.2 Bias Adjustment

#### 4.2.1 Local Bias Adjustment Factor

The co-location site annual mean NO<sub>2</sub> concentrations measured by the diffusion tubes and the continuous monitors are displayed in Table 3.

The AEA Diffusion Tube Precision Accuracy Bias Spreadsheet<sup>7</sup> tool was used to calculate bias adjustment factors for the co-location site. Continuous monitoring data was sourced from the London Air Quality Network (LAQN) website<sup>8</sup>. Further details can be found in Appendix C. An average bias adjustment factor of 0.82 was obtained and this value has been applied to all diffusion tube concentrations unless otherwise stated. The complete diffusion tube results without the application of a bias adjustment factor can be found in Appendix B.

#### Table 3 Comparisons of Diffusion Tube Measurement and Continuous Monitors at Co-located Site

Site Name	2014 Annual Mean NO <sub>2</sub> Concentration (µg/m <sup>3</sup> )				
one Name	Unadjusted Diffusion Tube	Continuous Monitor			
Lewisham – New Cross	51.5	42.1			

Monthly readings from the diffusion tubes were compared with concentration at Lewisham New Cross (Figure 1). This illustrates an over-reading by the tube with results being higher than the continuous analyser for several months. The exceptions to this are the first three months of 2014 and December 2014, where diffusion tubes were in good agreement with the continuous analyser concentration. The positive bias exhibited by the diffusion tubes at this location may be due to turbulence and inhomogeneities of sampled air. At locations close to sources of NO such as roadside and kerbside sites, within-tube chemical reactions of NO and  $O_3$  have been found to result in over-reading in relation to reference method<sup>9</sup>.

<sup>&</sup>lt;sup>7</sup> AEA Diffusion Tube Precision Accuracy Bias Spreadsheet. Downloaded from <u>http://laqm.defra.gov.uk/bias-adjustment-factors/local-bias.html</u> <u>17/02/2015</u>.

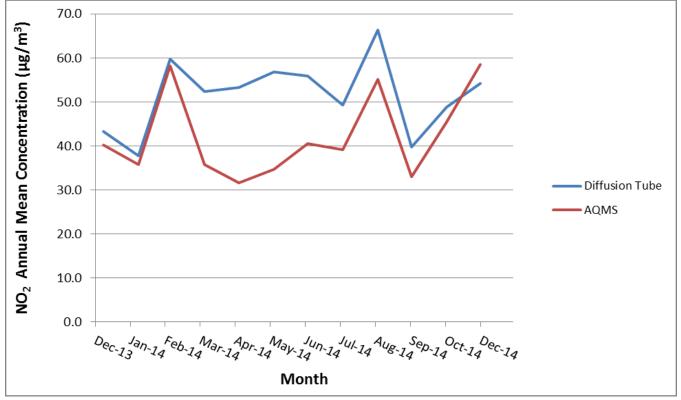

<sup>&</sup>lt;sup>8</sup> London Air Quality Network Website. Available at <u>http://www.londonair.org.uk</u>.

<sup>&</sup>lt;sup>9</sup> Cape, J.N., Review of the Use of Passive Diffusion Tubes for Measuring Concentrations of Nitrogen Dioxide in Air, 2005. Available at <u>http://uk-air.defra.gov.uk/reports/cat05/0810141025\_NO2\_review.pdf</u>

#### 4.2.2 National Bias Adjustment Factor

Due to the low value of the local bias adjustment factors in previous years, it was recommended that the bias adjustment factor obtained from national co-location studies<sup>10</sup> be calculated. The national bias adjustment factor for 2014 is 0.97 for the laboratory and preparation method, based on 9 studies (spreadsheet version 03/15).

Figure 1: Comparisons of Chemiluminescence and Diffusion Tube Measurements at AQMS New Cross for 2014

<sup>&</sup>lt;sup>10</sup> Defra, National Diffusion Tube Bias Adjustment Factor Spreadsheet, Spreadsheet Version Number: 03/14. Available at <a href="http://lagm.defra.gov.uk/bias-adjustment-factors/national-bias.html">http://lagm.defra.gov.uk/bias-adjustment-factors/national-bias.html</a>

#### 4.3 Annual Mean NO<sub>2</sub> Concentrations

The mean NO<sub>2</sub> concentration over the whole network during 2014 was 40.0  $\mu$ g/m<sup>3</sup> or, after applying a local bias adjustment of 0.82, 33.1  $\mu$ g/m<sup>3</sup>. The mean concentration calculated using the national bias adjustment factor was 38.8  $\mu$ g/m<sup>3</sup>; below the annual mean NO<sub>2</sub> objective of 40  $\mu$ g/m<sup>3</sup>. The maximum annual mean NO<sub>2</sub> concentration was measured at the L7 site at 65 Bell Green (46.8  $\mu$ g/m<sup>3</sup> using the co-location study bias adjustment factor, or 55.4  $\mu$ g/m<sup>3</sup> using the national bias adjustment factor). The second highest annual mean NO<sub>2</sub> concentration was measured LWS011 at Catford Hill (46.6  $\mu$ g/m<sup>3</sup> – co-location study bias adjusted or 55.1  $\mu$ g/m<sup>3</sup> – national bias adjusted). L7 and LWS011 are both roadside sites.

	Annual Mean NO <sub>2</sub> Concentration (μg/m <sup>3</sup> )						
Site Type	Raw	Bias Adjusted, using New Cross Co-located Tubes (Factor = 0.82)	Bias Adjusted, using National Bias Adjustment Factor (Factor = 0.97)				
All Sites	40.0	33.1	38.8				
Roadside	45.9	37.6	44.2				
Urban Background	32.3	26.5	31.3				

 Table 4
 Annual Mean NO<sub>2</sub> Concentration (Bias Adjusted), 2014

#### 4.3.1 Comparison with Limit Values and Objectives

The air quality objectives and limit values of relevance to NO<sub>2</sub> in the UK are detailed in Section 2. The results in Table 4, obtained after applying the co-location study adjustment factor, indicate that the annual mean NO<sub>2</sub> objective of 40  $\mu$ g/m<sup>3</sup> was not generally exceeded within the diffusion tube network during 2014. From Appendix B, it can be seen that at 7 of the 32 diffusion tube locations, the bias-adjusted annual mean NO<sub>2</sub> concentrations obtained after applying the co-location adjustment factor was greater than 40  $\mu$ g/m<sup>3</sup>. On the other hand, results based on the national bias adjustment factor, show that 13 sites exceeded the NO<sub>2</sub> annual mean objective.

A report issued by Air Quality Consultants<sup>11</sup> analysed the relationship between annual mean and hourly mean NO<sub>2</sub> concentrations, concluding that locations where the annual mean concentration is greater than 60  $\mu$ g/m<sup>3</sup> may be susceptible to breaches of the hourly mean objective (hourly mean NO<sub>2</sub> concentration of 200  $\mu$ g/m<sup>3</sup> or more not to be exceeded more than 18 occasions per year). After bias adjustment, there are no sites with measured NO<sub>2</sub> concentrations greater than 60  $\mu$ g/m<sup>3</sup> in 2014.

#### 4.3.2 Seasonal Variation

The seasonal variation in  $NO_2$  concentrations during 2014 are shown in Table 5 and Figure 2. Due to seasonal variations in the bias adjustment that can occur at diffusion tube sites, the results that have been presented are the raw concentrations with no bias adjustment applied.

The highest mean concentration occurred in March followed by September and November at roadside sites. For urban background sites, the highest mean concentrations were measured during March and November. Mean NO<sub>2</sub> concentration was the lowest in August for all site types.

<sup>&</sup>lt;sup>11</sup> Air Quality Consultants (2007). Deriving  $NO_2$  from  $NO_X$  for Air Quality Assessments of Roads.

# Table 5Monthly Mean NO2 Concentrations in Lewisham, 2014 (µg/m³; Unadjusted)

Site Type	Jan	Feb	Mar	Apr	Мау	Jun	Jul	Aug	Sep	Oct	Nov	Dec
All Sites	44.8	35.3	47.4	37.0	39.1	38.9	40.0	31.6	44.8	39.9	46.6	42.3
Roadside	48.7	39.3	51.9	42.2	46.6	46.5	47.9	36.0	51.8	45.4	51.4	45.7
Urban Background	38.1	27.5	40.3	28.9	28.3	26.3	27.7	24.6	35.5	31.7	40.0	37.5

Table 6 Unadjusted Winter and Summer Period Mean Concentrations in Lewisham, 2
--

Site Type	Winter Mean Concentration (October – March) (µg/m <sup>3</sup> )	Summer Mean Concentration (April – September) (µg/m³)	Ratio Winter : Summer
All Sites	42.7	38.6	1.1
Roadside	47.1	45.2	1.0
Urban Background	35.9	28.6	1.3

Table 6 shows that the ratio of winter to summer mean  $NO_2$  concentration was 1.0 for roadside sites, indicating mean concentrations were similar in the winter and summer periods. The urban background sites display a higher winter: summer ratio compared to roadside sites indicating higher mean concentrations in winter than in summer periods. The value was 1.3 in 2014. For all sites, collectively, the ratio of winter to summer mean  $NO_2$  concentration was 1.1.

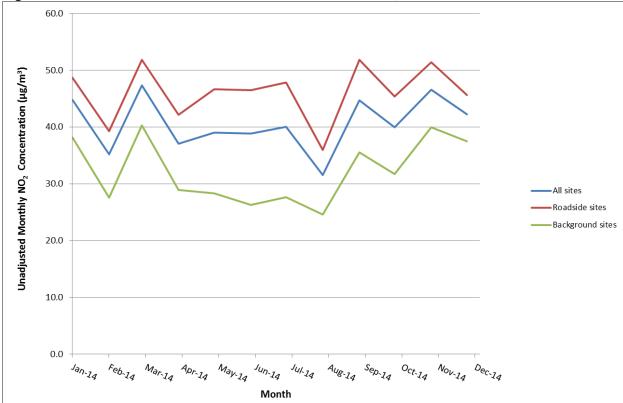

Figure 2: Seasonal Trend of NO<sub>2</sub> Concentrations in Lewisham, 2014

#### 4.4 Historical Trends

Table 7 summarises the results of the Lewisham Tube Network by site type from 2012 to 2014, results for each site in 2014 are detailed in Appendix B. These results have been bias adjusted and the factors can be found in Appendix C Table 9. Measurements from the past year showed an decrease in annual mean NO<sub>2</sub> concentration across the network between 2013 and 2014, with the network annual mean NO<sub>2</sub> concentration decreasing from  $39.1 \ \mu g/m^3$  in 2013 to  $33.1 \ \mu g/m$  in 2014 – local bias adjusted, and from 42.0  $\mu g/m^3$  in 2013 to 38.8  $\mu g/m^3$  in 2014 - national bias adjusted.

# Table 7 Annual Mean NO<sub>2</sub> Concentration (bias-adjusted) by Site Type, 2012 – 2014

Site Type	Bias Adjusted Annual Mean NO <sub>2</sub> Concentration (μg/m <sup>3</sup> )										
	20	12	20	13	2014						
	Bias Adjusted using New Cross Co- located tubes (Factor = 0.79)	Bias Adjusted using National Bias Adjustment factor (Factor = 1.01)	Bias Adjusted using New Cross Co- located tubes (Factor = 0.93)	Bias Adjusted using National Bias Adjustment factor (Factor =1.0)	Bias Adjusted using New Cross Co- located tubes (Factor = 0.82)	Bias Adjusted using National Bias Adjustment factor (Factor =0.97)					
All Sites	31.7	40.6	39.1	42.0	33.1	38.8					
Roadside	35.9	46.0	44.0	47.7	37.6	44.2					
Urban Background	25.6	32.7	31.9	33.7	26.5	31.3					

# 5 Conclusions

The main conclusions of the 2014 Lewisham Diffusion Tube Network study are:

 The mean NO<sub>2</sub> concentration for the whole network, based on local bias adjustment factor was 33.1 μg/m<sup>3</sup> or 38.8 μg/m<sup>3</sup> based on the national bias adjustment factor.

 $NO_2$  concentrations were greatest at roadside monitoring locations, followed by urban background sites. The highest annual mean  $NO_2$  concentration in 2014 was measured at site L7 (65 Bell Green). The mean concentration was 46.8  $\mu$ g/m<sup>3</sup> based on local bias adjustment factor, or 55.4  $\mu$ g/m<sup>3</sup> using the national bias adjustment factor. The second highest annual mean  $NO_2$  concentration occurred at LWS011 at Catford Hill with a value of 46.6  $\mu$ g/m<sup>3</sup> after applying the local bias adjustment factor or 55.1  $\mu$ g/m<sup>3</sup> – national bias adjusted.

- The mean roadside NO<sub>2</sub> concentration across the network was 37.6 μg/m<sup>3</sup>, based on the local bias adjustment factor, or 44.2 μg/m<sup>3</sup> based on the national bias adjustment factor, and the mean urban background concentration was 26.5 μg/m<sup>3</sup> using the local bias adjustment factor or 31.3 μg/m<sup>3</sup> using the national bias adjustment factor.
- Results based on the local adjustment factor show that 7 diffusion tube locations recorded annual mean NO<sub>2</sub> concentrations exceeding the annual mean NO<sub>2</sub> objective of 40 µg/m<sup>3</sup>. While results obtained after applying the national bias adjustment factor show that 13 sites exceeded the annual mean NO<sub>2</sub> objective.

#### Appendix C: Diffusion Tube Bias Adjustment

A local bias adjustment factor was calculated in order to apply bias correction to the raw diffusion tube results for 2014. Triplicate tubes were co-located alongside the continuous  $NO_2$  monitoring sites in New Cross Road (LW2), and this site has been used to calculate the bias adjustment factor 2014.

The continuous monitoring site listed above is part of the London Air Quality Network (LAQN reference is given in brackets).  $NO_2$  concentration data from the continuous monitoring sites between 08/01/2014 and 07/01/2015 to cover the period of diffusion tube monitoring was collated. Period mean  $NO_2$  concentrations were calculated for each diffusion tube exposure period during 2014. Data capture statistics for the same periods were also determined.

The continuous monitoring data and raw triplicate tube concentrations were inputted into the Bias Adjustment Calculator tool to calculate bias adjustment factors

The bias adjustment calculations for the monitoring site are shown in Figure 4. Table 9 provides a summary of the bias factor calculated for the site, and the comparison with national bias adjustment factors for the past years are also shown.

Table 9	Summary of Local and National Bias Adjustment Factors for Lewisham NO <sub>2</sub> Diffusion Tube
Surveys, 2	2008 to 2014

Year	Mean Local Factor	National Factor <sup>a</sup>
2009	0.84	0.97
2010	0.69	1.03
2011	0.59	0.95
2012	0.79	1.01
2013	0.93	1.00
2014	0.82	0.97

Notes: <sup>a</sup> National factor obtained from Bias Adjustment Factor spreadsheet<sup>3</sup> version 03/15 based on Gradko as the analysing laboratory using the 50% TEA in acetone method;

#### Seasonal Adjustment

Where data capture is less than 75% (found in 2014 at diffusion tube locations SCH21 and L10), the results have been annualised. Mean concentrations for the period covered by the diffusion tube monitoring and annual mean NO<sub>2</sub> concentrations have been collated from three nearby background continuous monitoring sites measuring NO<sub>2</sub> and with data capture rates greater than 90%. The average of the ratios between the period mean NO<sub>2</sub> concentrations and the annual mean NO<sub>2</sub> concentrations have been used to determine an adjustment factor, which has then been applied to the diffusion tube monitoring data to provide estimates of annual mean NO<sub>2</sub> concentrations at those locations.

Summary of 2014 Regional AURN NO <sub>2</sub> Data
